

The connections in the database are set up to make sense of things like, a customer is linked to a theater they visit often, and also to their address, so we know where they live. Then, an online user is tied to a customer, showing they're connected somehow. In addition, tickets connect to customers, users, movies, and theaters, keeping track of who's buying tickets for which movies and theaters. Addresses help us know where customers and theaters are located, with each address having its own unique ID. And theaters are associated with addresses, making it clear where each theater is situated. Finally, movies connect to theaters, showing which movies are playing in which theaters at any given time. These connections make it easy to understand how everything fits together and keeps the data organized.
